Phases of development for statistical methods

Tim Morris, MRC Clinical Trials Unit at UCL
Joint work with Georg Heinze, Anne-Laure Boulesteix, Michael Kammer and Ian White

Key idea

13 years ago, Ian White floated the core idea I am presenting today:
a methods development pipeline

I am absolutely not proposing regulation of statistical methods, but wonder…
How would we approach things if statistical methods were regulated?

ORIGINAL ARTICLE

A method was developed for correcting the bias in the usual study weights in meta-analyses

Stephen D. Walter[a,*], Narayanaswamy Balakrishnan[b]

[a]*Department of Health Research Methods, Evidence, and Impact, McMaster University, Hamilton, Ontario, Canada*

Accepted 29 August 2022; Published online 21 September 2022

Walter & Balakrishnan in brief

- The estimated (unscaled) weights in meta-analysis are biased upwards
- Find an expression for the bias and use this to derive a bias-correction
- Try it in two example meta-analyses with few, small studies; the weights are slightly different
- '*We recommend that our bias correction should be routinely adopted*' and '*Elimination of this bias will enhance the validity of conclusions from a meta-analysis, compared with the situation when the standard weights are used.*' ☺

Why do people not use new methods?

Why do people not use new methods?

A malevolent opponent?

It’s sometimes true that someone fundamentally disagrees with you and are actively working against your agenda (consider whether they have a good point)

Why do people not use new methods?

Why do people not use new methods?

‘They said it’s good in there and I should come… only they didn’t give me the key’

Let’s give applied researchers credit

Let’s start at the end. Applied researchers need to use a method that is suitable for their study, e.g. a trial I am designing, or this EHR dataset in front of me.

Suppose they are motivated to do something as well as they can, rather than just to get something past journal editors / regulators (which always amounts to precedence).

They might want to know **when a method is and is not preferred method; what diagnostics are available; pitfalls that may occur at application**.

Phases of drug development

PHASE I TRIALS: Initial studies to determine the metabolism and pharmacologic actions of drugs in humans, the side effects associated with increasing doses, and to gain early evidence of effectiveness; may include healthy participants and/or patients.
PHASE II TRIALS: Controlled clinical studies conducted to evaluate the effectiveness of the drug for a particular indication or indications in patients with the disease or condition under study and to determine the common short-term side effects and risks.
PHASE III TRIALS: Expanded controlled and uncontrolled trials after preliminary evidence suggesting effectiveness of the drug has been obtained, and are intended to gather additional information to evaluate the overall benefit-risk relationship of the drug and provide and adequate basis for physician labelling.
PHASE IV TRIALS: Post-marketing studies to delineate additional information including the drug's risks, benefits, and optimal use.

On the bias of various estimators of the logit and its variance with application to quantal bioassay

BY JOHN J. GART AND JAMES R. ZWEIFEL
National Cancer Institute, Bethesda, Md

SUMMARY

The bias of several logit estimators and their corresponding variance estimators is investigated in small samples. Their use in quantal bioassay is similarly explored.

Example: Firth's bias-correction for maximum likelihood estimators

Take separation in logistic regression, when log-odds ratios go to $\pm\infty$. So in finite samples, it's infinitely biased. Firth's correction corrects this bias.

A neat side effect is that it gives finite estimates of regression coefficients in GLMs even with data constellations where maximum likelihood estimates do not exist.

Phase I: derived correction and gave some simple examples

Biometrika (1993), 80, 1, *pp.* 27–38
Printed in Great Britain

Bias reduction of maximum likelihood estimates

BY DAVID FIRTH
Department of Mathematics, University of Southampton, SO9 5NH, U.K.

SUMMARY

It is shown how, in regular parametric problems, the first-order term is removed from the asymptotic bias of maximum likelihood estimates by a suitable modification of the score function. In exponential families with canonical parameterization the effect is to

Link to Stratos ‘levels’?

Arguably a method may be used with the dataset in front of you when it has not gone through all these phases.

There is perhaps a link to draw to Stratos ‘levels’, where we may be comfortable with level-3 researchers using methods that have gone through less rigorous testing than level-1 researchers.

‘What is the point of this talk?’

I hope that thinking about phases:

- Gives frustrated methods researchers doing ‘early-phase’ work a framework to understand why their method has not been universally adopted;
- Recognises ‘late-phase’ statistical methods research as valuable;
- Gives applied researchers a way to articulate their hesitation about using new methods.

Some encouragement

Points to ponder

- Can you think of a great/useful method that is still ‘sleeping’?
- What work would be needed to ‘awaken’ it?
- Do you regard late-phase work as ‘marketing’ for attention-seekers?!

Just out!
